Peculiar velocities from LF variations Basic concepts

 Peculiar motion introduces systematic variations in the observed luminosity distribution of galaxies (Nusser et al. 2011; Tammann et al. 1979)

$$M = M_{\rm obs} + 5\log_{10}\frac{D_L(z_{\rm obs})}{D_L(z)}$$

$$\frac{z_{\rm obs} - z}{1 + z_{\rm obs}} = V(t, r) - \Phi(t, r) - \text{ISW} \approx V(t, r)$$

Maximize probability of observing galaxies given their magnitudes and redshifts:

$$\log P_{\text{tot}} = \sum_{i} \log P_i(M_i | z_i, V_i) = \frac{\phi(M_i)}{\int_{a_i}^{b_i} \phi(M) dM}$$

Velocity models:

 $V(t, \mathbf{r}) \rightarrow V(\{x_i\}), \quad V(t, \mathbf{r}) \rightarrow V(\beta)$ (linear reconstruction; $\beta = f/b$)

Method independent of galaxy bias and traditional distance indicators

Methodology and data

Application to SDSS

Conclusions

SDSS Data Release 7 NYU Value-Added Galaxy Catalog (Blanton et al. 2005)

- Use r-band magnitudes (Petrosian)
- $14.5 < m_r < 17.6$
- $-22.5 < M_{\rm obs} < -17.0$
- 0.02 < *z* < 0.22
- $N \sim 5 \times 10^5$
- Adopt pre-Planck cosmological parameters (Calabrese et al. 2013)
- Realistic mocks for testing
 - \rightarrow SDSS footprint
 - \rightarrow photometric offsets between stripes

LF estimators "Non-parametric" spline-estimator of $\phi(M)$

Feix et al., JCAP 09 (2014) - arXiv:1405.6710

- Normalization unimportant for our analysis
- Two-parameter Schechter function does quite well
- To reduce errors, adopt more flexible form for $\phi(M)$
- Model φ(M) as a spline with sampling points {φ_j(M)} for M_j < M < M_{j+1}
- Advantage: smoothness, nice analytic properties for integrals / derivatives)
- Parameterize luminosity evolution:

$$e(z)=Q_0(z-z_0)+O\left(z^2\right)$$

Motivation 00000	Methodology and data	Application to SDSS	Conclusions
An example Redshift-binned ve	elocity model		

• Expand binned velocity field in SHs:

$$V(t, \mathbf{r}) \rightarrow \tilde{V}(\hat{\mathbf{r}}) \quad \tilde{V}(\hat{\mathbf{r}}) = \sum_{l,m} a_{lm} Y_{lm}(\hat{\mathbf{r}})$$

• For $N \gg 1$, P_{tot} is well approximated by a Gaussian (simplifies computation):

$$\log P_{\text{tot}}(\mathbf{d}|\mathbf{x}) \approx -\frac{1}{2}(\mathbf{x} - \mathbf{x}_0)^T \Sigma^{-1}(\mathbf{x} - \mathbf{x}_0) + \text{const}, \quad \text{where } \mathbf{x}^T = \left(\{q_j\}, \{a_{lm}\}\right)$$

 Marginalize over LF parameters {q_j} and construct posterior for C_l = (|a_{lm}|²) by applying Bayes' theorem:

$$P(\lbrace C_l \rbrace) \propto \int P(\mathbf{d}|\lbrace a_{lm} \rbrace) P(\lbrace a_{lm} \rbrace|\lbrace C_l \rbrace) da_{lm}$$

- Assume {a_{lm}} as normally distributed
- For a Λ CDM model prior, $C_l = C_l(\{c_k\})$:

$$C_{l} = \frac{2}{\pi} \int dk k^{2} P_{\Phi}(k) \left| \int dr W(r) \left(\frac{lj_{l}}{r} - kj_{l+1} \right) \right|^{2}$$

Linear velocity reconstruction Growth constraints at $z \sim 0.1$

Application to SDSS ●○○

Building the velocity field of SDSS galaxies Linear velocity reconstruction (Nusser & Davis 1994; Nusser et al. 2012)

- Reconstruct the large-scale velocity field as a function of $\beta = f/b$
- Assume $\beta = \text{const}$ over sample range
- Smooth redshift-space density field on a scale $R_s \sim 10h^{-1}$ Mpc
- Problem in "harmonic" space:

$$\frac{1}{s^2}\frac{\mathrm{d}}{\mathrm{d}s}\left(s^2\frac{\mathrm{d}\Phi_{lm}}{\mathrm{d}s}\right) - \frac{1}{1+\beta}\frac{l(l+1)\Phi_{lm}}{s^2} = \frac{\beta}{1+\beta}\left(\delta_{lm}^g - \frac{\mathrm{d}\log S}{\mathrm{d}s}\frac{\mathrm{d}\Phi_{lm}}{\mathrm{d}s}\right)$$

- Boundary conditions: set $\delta = 0$ outside data volume (zero-padding)
- Must exclude monopole and dipole terms
- Models robust w.r.t. small-scale issues, e.g. details of galaxy bias
- Assign galaxy velocities for discrete β -values \rightarrow likelihood analysis

- 3 Application to SDSS
- 4 Conclusions

▲ロト ▲ 同 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

- ML estimators extracting the large-scale velocity field through spatial modulations in the observed LF of galaxies offer a powerful and complementary alternative to currently used methods
- New growth measurements are in agreement with the results from Planck
- Luminosity-based constraints on the growth rate at $z \sim 0.1$ are both **compatible** and **consistent** with those coming from RSD analyses of similar datasets
- Consistency is striking in view of the different possible systematic biases associated with the different methods
- Luminosity-based techniques are less sensitive to nonlinear corrections than the two-point statistics which enter the analysis of RSDs
